Homework 2, Intro to NLP, 2017

This is due at 11pm on Tuesday, October 10. Please see detailed submission instructions below. 100 points total.

How to do this problem set:

- What version of Python should I use? 2.7
- Most of these questions require writing Python code and computing results, and the rest of them have textual answers. To generate the answers, you will have to fill out supporting files, vit_starter.py,classperc.py and structperc.py.
- Write all the answers in this ipython notebook. Once you are finished (1) Generate a PDF via (File -> Download As -> PDF) and upload to Gradescope (2)Turn in vit_starter.py, classperc.py, structperc.py and hw_2.ipynb on Moodle
- Important: Check your PDF before you turn it in to gradescope to make sure it exported correctly. If ipython notebook gets confused about your syntax it will sometimes terminate the PDF creation routine early. You are responsible for checking for these errors. If your whole PDF does not print, try running \$jupyter nbconvert --to pdf hw_1.ipynb to identify and fix any syntax errors that might be causing problems.
- Important: When creating your final version of the PDF to hand in, please do a fresh restart and execute every cell in
 order. Then you'll be sure it's actually right. One convenient way to do this is by clicking Cell -> Run All in the
 notebook menu.

Academic honesty

- We will audit the Moodle code from a few dozen students, chosen at random. The audits will check that the code you wrote
 and turned on Moodle generates the answers you turn in on your Gradescope PDF. If you turn in correct answers on your
 PDF without code that actually generates those answers, we will consider this a potential case of cheating. See the course
 page for honesty policies.
- We will also run automatic checks of code on Moodle for plagiarism. Copying code from others is considered a serious
 case of cheating.

1. HMM (15 points)

Answer the following questions using the transition matrix T and emission probabilities E below. Below, Δ and \Box are two output variables, A and B are two hidden states; s_n refers to the n^{th} hidden state in the sequence and o_n refers to the n^{th} observation.

$$T = egin{array}{c|cccc} A & B & END \\ \hline START & 0.5 & 0.5 & 0.0 \\ A & 0.2 & 0.3 & 0.5 \\ B & 0.4 & 0.4 & 0.2 \\ \hline \end{array}$$

$$E = \begin{array}{c|cc} & \Delta & \Box \\ \hline A & 0.5 & 0.5 \\ B & 0.3 & 0.7 \end{array}$$

For all the questions in this section, write answer and show your work.

Question 1.1 (2 points)

Does
$$P(o_2 = \Delta | s_1 = B) = P(o_2 = \Delta | o_1 = \Box)$$
?

$$P(o_2 = \Delta | s_1 = B) = 0.4 * 0.5 + 0.4 * 0.3 = 0.32$$

$$P(o_2 = \Delta | o_1 = \Box) = (0.5*0.5 + 0.5*0.7)*((0.2*0.5 + 0.3*0.3) + (0.4*0.3 + 0.4*0.5)) = 0.306$$

(getting a square on the 1st) (getting triangle on the second)

Hence they are not equal.

Question 1.2 (2 points)

Does
$$P(s_2 = B|s_1 = A) = P(s_2 = B|s_1 = A, o_1 = \Delta)$$
?

Yes they are equal. Since the the information from s_1 is already provided, the observing of o_1 will not impact the probability of $s_2 = B$.

Question 1.3 (3 points)

Does
$$P(o_2 = \Delta | s_1 = A) = P(o_2 = \Box | s_1 = A, s_3 = A)$$

No. They are not equal. Knowing the state s_3 can help one decide what s_2 could have been. In this example, is s_3 = A then there is a higher probability that $s_2 = B$ than $s_2 = A$.

Question 1.4 (3 points)

Compute the probability of observing \square as the first emission of a sequence generated by an HMM with transition matrix T and emission probabilities E.

$$P(o_1 = \Box) = P(s_1 = A) * P(\Box A) + P(s_1 = B) * P(\Box B) = 0.5 * 0.5 + 0.5 * 0.7 = 0.6$$

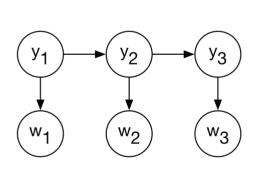

Question 1.5 (5 points)

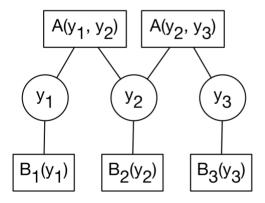

Compute the probability of the first state being A given that the last token in an observed sequence of length 2 was the token Δ .

$$P(s_1 = A | o_2 = \Delta) = P(s_1 = A | s_2 = A) * P(s_2 = A | o_2 = \Delta) + P(s_1 = A | s_2 = B) * P(s_2 = B | o_2 = \Delta)$$

= $((0.5/0.8) * (0.2/0.6)) + ((0.3/0.8) * (0.3/0.7)) = 0.369$

2. Viterbi (log-additive form) (20 points)

One HMM chain is shown on the left. The corresponding **factor graph** version is shown on the right. This simply shows the structure of the A and B_t log-prob tables and which variables they express preferences over. A is the **transition factor** that has preferences for the two neighboring variables; for example, $A(y_1, y_2)$ shows how happy the model is with the transition from y_1 to y_2 . The same transition preference function is used at all positions (t-1,t) for each t=2..T. B_t is the **emission factor** that has preferences for the variable y_t . As a goodness function it is e.g. $B_1(y_1)$, $B_2(y_2)$, etc.

Let $\vec{y} = (y_1, y_2, \dots, y_T)$ a proposed tag sequence for a T length sentence. The total goodness function for a solution \vec{y} is

$$G(\vec{y}) = \sum_{t=1}^{T} B_t(y_t) + \sum_{t=2}^{T} A(y_{t-1}, y_t)$$

Question 2.1 (2 points)

Define A and B_r in terms of the HMM model, such that G is the same thing as $\log p(\vec{y}, \vec{w})$ under the HMM.

$$B_t(y_t) = log \ p(w_t|y_t)$$

$$A(y_{t-1}, y_t) = log \ p(y_t|y_{t-1})$$

Question 2.2 (18 points)

Implement additive log-space Viterbi by completing the **viterbi()** function. It takes in tables that represent the A and B functions as input. We give you an implementation of G() in **vit_starter**, you can check to make sure you understand the data structures, and also the exhaustive decoding algorithm too. Feel free to add debugging print statements as needed. The main code runs the exercise example by default.

When debugging, you should make new A and B examples that are very simple. This will test different code paths. Also you can try the **randomized_test()** from the starter code.

Look out for negative indexes as a bug. In python, if you use an index that's too high to be in the list, it throws an error. But it will silently accept a negative index ... it interprets that as indexing from the right.

```
In [2]: %load_ext autoreload %autoreload 2
```

In [1]: # Implement the viterbi() function in vit_starter.py and then run this cell to show your outpu

from vit_starter import *

if __name__ == '__main__ ':
 A = {(0,0):3, (0,1):0, (1,0):0, (1,1):3}
 Bs= [[0,1], [0,1], [30,0]]
 # that's equivalent to: [{0:0,1:1}, {0:0,1:1}, {0:30,1:0}]

y = exhaustive(A, Bs, set([0,1]))
 print "Exhaustive decoding:", y
 print "score:", goodness_score(y, A, Bs)
 y = viterbi(A, Bs, set([0,1]))
 print "Viterbi decoding:", y

```
Exhaustive decoding: [0, 0, 0] score: 36
Viterbi decoding: [0, 0, 0]
```

Copy and paste the viterbi function that you implemented in vit_starter.py.

```
In [2]: def viterbi(A factor, B factors, output vocab):
            A_factor: a dict of key:value pairs of the form
                {(curtag,nexttag): score}
            with keys for all K^2 possible neighboring combinations,
            and scores are numbers. We assume they should be used ADDITIVELY, i.e. in log space.
            higher scores mean MORE PREFERRED by the model.
            B_factors: a list where each entry is a dict {tag:score}, so like
            [ {Noun: -1.2, Adj: -3.4}, {Noun: -0.2, Adj: -7.1}, ....]
            each entry in the list corresponds to each position in the input.
            output vocab: a set of strings, which is the vocabulary of possible output
            symbols.
            RETURNS:
            the tag sequence yvec with the highest goodness score
            N = len(B factors)
                                  # length of input sentence
            # viterbi log-prob tables
            V = [{tag:0 for tag in output vocab} for t in range(N)]
            # backpointer tables
            # back[0] could be left empty. it will never be used.
            back = [{tag:None for tag in output_vocab} for t in range(N)]
            # todo implement the main viterbi loop here
            # you may want to handle the t=0 case separately
            for t in range(N):
                for tag in output vocab:
                    if t==0:
                        V[t][tag]=B_factors[t][tag]
                    else:
                        maxi=0
                        sel i=tag
                        for j in output vocab:
                             temp=(V[t-1][j]+A factor[(j,tag)]+B factors[t][tag])
                            if temp>maxi:
                                 maxi=temp
                                 sel j=j
                        V[t][tag]=maxi
                        back[t][tag]=sel j
            path=[dict_argmax(V[-1])]
            output vocab=list(output vocab)
            for i in range(N-1,0,-1):
                path.append(back[i][path[-1]])
            pathrev=path[::-1]
            return pathrev
```

3. Averaged Perceptron (5 points)

We will be using the following definition of the perceptron, which is the multiclass or structured version of the perceptron. The training set is a bunch of input-output pairs (x_i, y_i) . (For classification, y_i is a label, but for tagging, y_i is a sequence). The training algorithm is as follows:

For T iterations, iterate through each (x_i, y_i) pair in the dataset, and for each,

```
1. Predict y^* := \arg \max_{y'} \theta^T f(x_i, y')
2. If y_i \neq y^*: then update \theta := \theta^{(old)} + rg
```

where r is a fixed step size (e.g. r=1) and g is the *gradient vector*, meaning a vector that will get added into θ for the update, specifically

$$g = \underbrace{f(x_i, y_i)}_{\text{feats of true output}} - \underbrace{f(x_i, y^*)}_{\text{feats of predicted output}}$$

Both in theory and in practice, the predictive accuracy of a model trained by the structured perceptron will be better if we use the average value of θ over the course of training, rather than the final value of θ . This is because θ wanders around and doesn't converge (typically), because it overfits to whatever data it saw most recently. After seeing t training examples, define the averaged parameter vector as

$$\bar{\theta}_t = \frac{1}{t} \sum_{t'=1}^t \theta_{t'} \tag{1}$$

where $\theta_{t'}$ is the weight vector after t' updates. (We are counting t by the number of training examples, not passes through the data. So if you had 1000 examples and made 10 passes through the data in order, the final time you see the final example is t=10000.) For training, you still use the current θ parameter for predictions. But at the very end, you return the $\bar{\theta}$, not θ , as your final model parameters to use on test data.

Directly implementing equation (1) would be really slow. So here's a better algorithm. This is the same as in Hal Daume's CIML chapter on perceptrons, but adapted for the structured case (as opposed to Daume's algorithm, which assumes binary output). Define g_t to be the update vector g as described earlier. The perceptron update can be written

$$\theta_t = \theta_{t-1} + rg_t$$

Thus the averaged perceptron algorithm is, using a new 'weightsums' vector S,

- 1. Initialize $t = 1, \theta_0 = \vec{0}, S_0 = \vec{0}$
- 2. For each example i (iterating multiples times through dataset),
 - Predict $y^* = \arg \max_{y'} \theta^T f(x_i, y')$
 - Let $g_t = f(x_i, y_i) f(x_i, y^*)$
 - Update $\theta_t = \theta_{t-1} + rg_t$
 - Update $S_t = S_{t-1} + (t-1)rg_t$
 - t := t + 1
- 3. Calculate $\bar{\theta}$ based on S

In an actual implementation, you don't keep old versions of S or θ around ... above we're using the t subscripts above just to make the mathematical analysis clearer.

Our proposed algorithm computes $\bar{\theta}_t$ as

$$\bar{\theta}_t = \theta_t - \frac{1}{t} S_t \tag{2}$$

For the following problems, feel free to set r = 1 just to simplify them.

For following questions write only math answers, no code required.

Question 3.1 (1 point)

What is the computational advantage of computing θ using Equation (2) instead of directly implementing Equation (1)?

In equation (1), $\bar{\theta}$ is calculated by iterating over t' updates which would take linear time in t' whereas, in equation (2), $\bar{\theta}$ is just a simple subtraction as the vector S is maintained as a running sum.

Now we'll show this works, at least for early iterations.

Question 3.2 (1 point)

What are $\bar{\theta}_1$, $\bar{\theta}_2$, $\bar{\theta}_3$, and $\bar{\theta}_4$? Please derive them from the Equation (1) definition, and state them in terms of g_1 , g_2 , g_3 , and/or g_4 .

$$\bar{\theta}_1 = \theta_1$$

$$\bar{\theta}_2 = (\theta_1 + \theta_2)/2$$

$$\bar{\theta}_3 = (\theta_1 + \theta_2 + \theta_3)/3$$

$$\begin{split} \bar{\theta}_4 &= (\theta_1 + \theta_2 + \theta_3 + \theta_4)/4 \\ \theta_2 &= \theta_1 + \gamma g_2 \\ \theta_3 &= \theta_2 + \gamma g_3 = \theta_1 + \gamma g_2 + \gamma g_3 \\ \theta_4 &= \theta_3 + \gamma g_4 = \theta_1 + \gamma g_2 + \gamma g_3 + \gamma g_4 \\ \bar{\theta}_1 &= \theta_1 \\ \bar{\theta}_2 &= (2\theta_1 + \gamma g_2)/2 \\ \bar{\theta}_3 &= (3\theta_1 + 2\gamma g_2 + \gamma g_3)/3 \end{split}$$

 $\bar{\theta}_4 = (4\theta_1 + 3\gamma g_2 + 2\gamma g_3 + \gamma g_4)/4$

Question 3.3 (1 point)

What are S_1 , S_2 , S_3 , and S_4 ? Please state them in terms of g_1 , g_2 , g_3 , and/or g_4 .

$$S_1 = S_0 + 0 \gamma g_1$$

$$S_2 = S_1 + 1 \gamma g_2 = S_0 + \gamma g_2$$

$$S_3 = S_2 + 2 \gamma g_3 = S_0 + \gamma g_2 + 2 \gamma g_3$$

$$S_4 = S_3 + 3 \gamma g_4 = S_0 + \gamma g_2 + 2 \gamma g_3 + 3 \gamma g_4$$

Question 3.4 (2 points)

Show that Equation (2) correctly computes $\bar{\theta}_3$ and $\bar{\theta}_4$.

$$\begin{split} \bar{\theta}_3 &= \theta_3 - \frac{1}{3}S_3 \\ \bar{\theta}_3 &= \theta_1 + \gamma g_2 + \gamma g_3 - \frac{1}{3}(S_0 + \gamma g_2 + 2\gamma g_3) \\ &= \frac{1}{3} * (3\theta_1 + 3\gamma g_2 + 3\gamma g_3 - S_0 - \gamma g_2 - 2\gamma g_3) \\ &= \frac{1}{3}(3\theta_1 + 2\gamma g_2 + \gamma g_3 - S_0) \\ &= \frac{1}{3}(3\theta_1 + 2\gamma g_2 + \gamma g_3) \\ &= \bar{\theta}_3 \\ \bar{\theta}_4 &= \theta_4 - \frac{1}{4}S_4 \\ \bar{\theta}_4 &= \theta_1 + \gamma g_2 + \gamma g_3 + \gamma g_4 - \frac{1}{4}(S_0 + \gamma g_2 + 2\gamma g_3 + 3\gamma g_4) \\ &= \frac{1}{4}(4\theta_1 + 4\gamma g_2 + 4\gamma g_3 + 4\gamma g_4 - S_0 + \gamma g_2 + 2\gamma g_3 + 3\gamma g_4) \\ &= \frac{1}{4}(4\theta_1 + 3\gamma g_2 + 2\gamma g_3 + 1\gamma g_4 - S_0) \\ &= \frac{1}{4}(4\theta_1 + 3\gamma g_2 + 2\gamma g_3 + 1\gamma g_4) \\ &= \bar{\theta}_4 \end{split}$$

Question 3.5 (2 Extra Credit points)

Use proof by induction to show that this algorithm correctly computes $\bar{\theta}_t$ for any t.

$$\bar{\theta}_1 = \theta_1$$

 $\bar{\theta}_1 = \theta_1 - \frac{1}{1}S_0 \text{ Valid for P=0.}$ $S_0 = \bar{0}$ $\Rightarrow \bar{\theta}_1 = \theta_1$ for P=k, Hypothesis is P=k is valid. $\theta_k = (\theta_1 + \gamma g_2 + \gamma g_3 \dots \gamma g_k)$ $\bar{\theta}_k = \theta_k - \frac{1}{k}S_k$ $S_k = S_{k-1} + (k-1)\gamma g_k$ $\bar{\theta}_k = (k\theta_1 + (k-1)\gamma g_2 + \dots + \gamma g_k)/k$ Show that P=k+1 is valid: $\theta_{k+1} = (\theta_1 + \gamma g_2 + \gamma g_3 \dots \gamma g_k) + (\gamma g_{k+1})$ $S_{k+1} = S_k + \gamma g_{k+1}$ $\bar{\theta}_{k+1} = \theta_{k+1} - \frac{1}{k+1}S_{k+1}$ $\bar{\theta}_{k+1} = \theta_k + \gamma g_{k+1} - \frac{1}{k+1}(S_k + \gamma g_{k+1})$ $\bar{\theta}_{k+1} = ((k+1)\theta_k + (k+1)\gamma g_{k+1} - S_k - \gamma g_{k+1})/(k+1)$ Since $S_k = k(\theta_k - \bar{\theta_k})$

$$\bar{\theta}_{k+1} = ((k+1)\theta_k + (k+1)\gamma g_{k+1} - k(\theta_k - \bar{\theta_k}) - \gamma g_{k+1})/(k+1)$$

$$\bar{\theta}_{k+1} = ((k+1)\theta_k + (k+1)\gamma g_{k+1} - k(\theta_k - \theta_k) - \gamma g_{k+1})/(k+1)$$

$$\bar{\theta}_{k+1} = ((k+1)\theta_k + \gamma g_{k+1} - k\theta_k + k\bar{\theta}_k))/(k+1)$$

$$\bar{\theta}_{k+1} = ((k+1)\theta_k + \gamma g_{k+1}) / (k+1)$$

$$\bar{\theta}_{k+1} = (\theta_k + k\bar{\theta}_k + \gamma g_{k+1}) / (k+1)$$

$$\bar{\theta}_{k+1} = ((\theta_1 + \gamma g_2 + \gamma g_3 \dots \gamma g_k) + (k\theta_1 + (k-1)\gamma g_2 + \dots + \gamma g_k) + \gamma g_{k+1}))/(k+1)$$

$$\bar{\theta}_{k+1} = ((k+1)\theta_1 + k\gamma g_2 + \dots + 2\gamma g_k) + \gamma g_{k+1}))/(k+1)$$

$$\bar{\theta}_{k+1} = \bar{\theta}_{k+1}$$

4. Classifier Perceptron (20 points)

Implement the averaged perceptron for document classification, using the same sentiment analysis dataset as you used for HW1. On the first two questions, we're asking you to develop using only a subset of the data, since that makes debugging easier. On the third question, you'll run on the full dataset, and you should be able to achieve a higher accuracy compared to your previous Naive Bayes implementation. Starter code is provided in classperc.py.

Question 4.1 (8 points)

Implement the simple, non-averaged perceptron. Run your code on **the first 1000 training instances** for 10 passes through the training data. For each pass, report **the training and test set accuracies**.

Report only accuracy values here, no code Training iteration 0 TR RAW EVAL: 1492/2000 = 0.7460 accuracy DEV RAW EVAL: 1351/2000 = 0.6755 accuracy Training iteration 1 TR RAW EVAL: 1774/2000 = 0.8870 accuracy DEV RAW EVAL: 1537/2000 = 0.7685 accuracy Training iteration 2 TR RAW EVAL: 1839/2000 = 0.9195 accuracy DEV RAW EVAL: 1556/2000 = 0.7780 accuracy Training iteration 3 TR RAW EVAL: 1731/2000 = 0.8655 accuracy DEV RAW EVAL: 1444/2000 = 0.7220 accuracy Training iteration 4 TR RAW EVAL: 1834/2000 = 0.9170 accuracy DEV RAW EVAL: 1498/2000 = 0.7490 accuracy Training iteration 5 TR RAW EVAL: 1916/2000 = 0.9580 accuracy DEV RAW EVAL: 1568/2000 = 0.7840 accuracy Training iteration 6 TR RAW EVAL: 1965/2000 = 0.9825 accuracy DEV RAW EVAL: 1580/2000 = 0.7900 accuracy Training iteration 7 TR RAW EVAL: 1868/2000 = 0.9340 accuracy DEV RAW EVAL: 1517/2000 = 0.7585 accuracy Training iteration 8 TR RAW EVAL: 1954/2000 = 0.9770 accuracy DEV RAW EVAL: 1592/2000 = 0.7960 accuracy Training iteration 9 TR RAW EVAL: 1888/2000 = 0.9440 accuracy DEV RAW EVAL: 1501/2000 = 0.7505 accuracy [learned weights for 77848 features from 2000 examples.]

Question 4.2 (8 points)

Implement the averaged perceptron. Run your code on **the first 1000 training instances** for 10 passes through the training data. For each pass, compute the $\bar{\theta}$ so far, and report its **test set accuracy**.

```

```

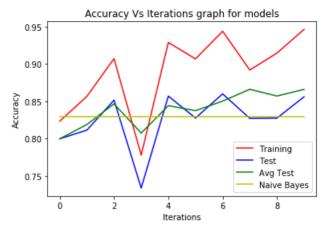

Question 4.3 (4 points)

Graph four curves on the same plot, using the full dataset:

- · accuracy of the vanilla perceptron on the training set
- accuracy of the vanilla perceptron on the test set
- · accuracy of the averaged perceptron on the test set
- accuracy of your Naive Bayes classifier from HW1 (you don't need to re-run it; just take the best accuracy from your previous results).

The x-axis of the plot should show the number of iterations through the training set and the y-axis should show the accuracy of the classifier. For this part of the HW run your code on **the entire dataset** (all instances). Since Naive Bayes doesn't require multiple passes through the data just produce a single horizontal line showing its overall accuracy. Make sure your plot has a title, a label on the x-axis, a label on the y-axis and a legend showing which line is which. Explain verbally what's happening in this plot.

hw 2

5. Structured Perceptron with Viterbi (40 points)

In this problem, you will implement a part-of-speech tagger for Twitter, using the structured perceptron algorithm. Your system will be not too far off from state of the art performance, coding it all up yourself from scratch!

The dataset comes from http://www.ark.cs.cmu.edu/TweetNLP/ (http://www.ark.cs.cmu.edu/TweetNLP/) and is described in the papers listed there (Gimpel et al.~2011 and Owoputi et al.~2013). The Gimpel article describes the tagset; the annotation guidelines on that webpage describe it futher.

Your structured perceptron will use your Viterbi implementation from 2.2 as a subroutine. If that's buggy, this will cause many problems here---your perceptron will have really weird behavior. (This happened to us when designing your assignment!) If you have problems, try using the greedy decoding algorithm, which we provide in the starter code. Make sure to note which decoding algorithm you're using in your writeup.

The starter code is structperc.py and it assumes the two data files oct27.train and oct27.dev are in the same directory. (For simplicity we're just going to use this dev set as our test set.)

Question 5.1 (2 points)

First let's do a little data analysis to establish the **most common tag** baseline accuracy. Using a small script, load up the dev dataset (oct27.dev) using the function structperc.read_tagging_file (from import structperc). Calculate the following: What is the most common tag, and what would your accuracy be if you predicted it for all tags?

```
In [3]: ##Write your code here and show the output
import structperc
from collections import defaultdict
file=structperc.read_tagging_file('oct27.dev')
tags=defaultdict(int)
total=0
for line in file:
    for sym in line[1]:
        tags[sym]+=1
        total+=1
print max(tags.values())*1.0/total
```

0.155712212316

The structured perceptron algorithm works very similarly as the classification version you did in the previous question, except the prediction function uses Viterbi as a subroutine, which has to call feature extraction functions for local emissions and transition factors. There also has to be a large overall feature extraction function for an entire structure at once. The following parts will build up these pieces. First, we will focus on inference, not learning.

Question 5.2 (2 points)

We provide a barebones version of local_emission_features, which calculates the local features for a particular tag at a token position. You can run this function all by itself. Make up an example sentence, and call this function with it, giving it a particular index and candidate tag. Show the code for the function call you made and the function's return value, and explain

what the features mean (just a sentence or two).

In [4]: ##Show the code for function call with output
import structperc
print structperc.local_emission_features(0,'N',['desk','you'])

```
{'tag=N_curword=desk': 1, 'tag=N_biasterm': 1}
```

The function local_emission_features takes as input the token position, label and the token list. It returns a dictionary of two items containing the emission of the word-label pair and also a bias term for the label given. This basically assigns those emissions '1' for the input token and label provided and lets other features be.

Question 5.3 (2 points)

Implement features_for_seq(), which extracts the full feature vector f(x, y), where x is a sentence and y is an entire tagging sequence for that sentence. This will add up the feature vectors from each local emissions features for every position, as well as transition features for every position (there are N-1 of them, of course). Show the output on a very short example sentence and example proposed tagging, that's only 2 or 3 words long.

To define f(x,y) a little more precisely: If $f^{(B)}(t,x,y)$ means the local emissions feature vector at position t (i.e. the local_emission_features function), and $f^{(A)}(y_{t-1},y_t,y)$ is the transition feature function for positions (t-1,t) (which just returns a feature vector where everything is zero, except a single element is 1), then the full sequence feature vector will be the vector-sum of all those feature vectors:

$$f(x, y) = \sum_{t}^{T} f^{(B)}(t, x, y) + \sum_{t=2}^{T} f^{(A)}(y_{t-1}, y_t)$$

You implemented $f^{(B)}$ above. You probably don't need to bother implementing $f^{(A)}$ as a standalone function. You will have to decide on a particular convention to encode the name of a transition feature. For example, one way to do it is with string concatenation like this, "trans_%s_%s" % (prevtag, curtag), where prevtag and curtag are strings. Or you could use a python tuple of strings, which works since tuples have the ability to be keys in a python dictionary.

In other words: the emissions and transition features will all be in the same vector, just as keys in the dictionary that represents the feature vector. The transition features are going to be the count of how many times a particular transition (tag bigram) happened. The emissions features are going to be the vector-sum of all the local emission features, as calculated from local emission features.

In [5]: ##Show the call to your function and output
import structperc
print structperc.features_for_seq(['finna','get','good'],['V','N','D'])

```
{'tag=D_curword=good': 1, 'tag=D_biasterm': 1, 'tag=V_curword=finna': 1, 'tag=N_biasterm': 1,
'trans N D': 1, 'trans V N': 1, 'tag=N curword=get': 1, 'tag=V biasterm': 1}
```

Question 5.4 (4 points)

Look at the starter code for calc_factor_scores, which calculates the A and B score functions that are going to be passed in to your Viterbi implementation from problem 2, in order to do a prediction. The only function it will need to call is local_emission_features. It should NOT call features_for_seq. Why not?

Bscores requires only emmission probabilites and Ascores are the weights adjusted by the perceptron. The scoring function has local decomposition and hence the features used by Bscores are only local emissions and the feature - weight scoring is already stored in the dictionary weights as the structured perceptron is the adjusting those.

Question 5.5 (6 points)

Implement calc_factor_scores. Make up a simple example (2 or 3 words long), with a simple model with at least some nonzero features (you might want to use a defaultdict(float), so you don't have to fill up a dict with dummy values for all possible transitions), and show your call to this function and the output.

In [10]: ##Show the call to your function and output
import structperc

from collections import defaultdict

W=defaultdict(float)

W={'tag=V curword=The':0.1,'tag=N curword=dog':0.9,'trans V N':0.5}

a,b=structperc.calc_factor_scores(['The','dog'],W)

print 'Ascores' , a

print 'Bscores', b

```
Ascores {('D', '^'): 0, ('M', '@'): 0, ('^', '&'): 0, ('N', '#'): 0, ('G', 'G'): 0, ('X',
 'D'): 0, ('#', 'U'): 0, ('E',
                                  'M'): 0, (',', 'U'): 0, ('S', '&'): 0, ('A', 'Y'): 0, ('R',
                                                                    '!'): 0, ('@', '#'): 0, ('0',
                                                                                      'X'): 0, ('A'
 'N'): 0, ('T',
                                                                                     '!'): 0,
                  '@'): 0, ('M',
 'V'): 0, ('0',
                 '0'): 0, ('V',
                                   'X'): 0, ('G', 'E'): 0, ('E',
                                                                    'D'): 0, ('&',
                                                                                      '&'): 0, ('!'

Question 5.6 (4 points)

Implement predict_seq(), which predicts the tags for an input sentence, given a model. It will have to calculate the factor scores, then call Viterbi as a subroutine, then return the best sequence prediction. If your Viterbi implementation does not seem to be working, use the implementation of the greedy decoding algorithm that we provide (it uses the same inputs as vit starter.viterbi()).

OK, you're done with the inference part. Time to put it all together into the parameter learning algorithm and see it go.

Question 5.7 (14 points)

Implement train(), which does structured perceptron training with the averaged perceptron algorithm. You should train on oct27.train, and evaluate on oct27.dev. You will want to first get it working without averaging, then add averaging to it. Run it for 10 iterations, and print the devset accuracy at each training iteration. Note that we provide evaluation code, which assumes

predict seg() and everything it depends on is working properly.

For us, here's the performance we get at the first and last iterations, using the features in the starter code (just the bias term and the current word feature, without case normalization).

```
Training iteration 0

DEV RAW EVAL: 2556/4823 = 0.5300 accuracy

DEV AVG EVAL: 2986/4823 = 0.6191 accuracy

...

Training iteration 9

DEV RAW EVAL: 3232/4823 = 0.6701 accuracy

DEV AVG EVAL: 3341/4823 = 0.6927 accuracy

Learned weights for 24361 features from 1000 examples

        3291/4823 = 0.6824 accuracy
```

Question 5.8 (6 points)

Print out a report of the accuracy rate for each tag in the development set. We provided a function to do this fancy_eval. Look at the two sentences in the dev data, and in your writeup show and compare the gold-standard tags versus your model's predictions for them. Consult the tagset description to understand what's going on. What types of things does your tagger get right and wrong?

To look at the examples, you may find it convenient to use show_predictions (or write up the equivalent manually). For example, after 1 iteration of training, we get this output from the first sentence in the devset. (After investigating TV shows that were popular in 2011 when the tweet was authored, we actually think some of the gold-standard tags in this example might be

wrong.)

word	gold	pred		
@ciaranyree	@	@		
it	0	0		
was	٧	V		
on	Р	Р		
football	N	^	***	Error
wives	N	N		
,	,	,		
one	\$	\$		
of	Р	Р		
the	D	D		
players	N	N		
and	&	&		
his	D	D		
wife	N	N		
own	٧	V		
smash	^	D	***	Error
burger	^	N	***	Error

To do this part, you may find it useful to save your model's weights with pickle.dumps (or json.dumps) and have a short analysis script that loads the model and devdata to do the reports. If you have to re-train each time you tweak your analysis code, it can be annoying.

party

????? , ,

The model evaluates most of the words correctly. This includes words that usually not have multiple labels possible.

For example, the word 'wearing'l -V, 'loses'-V,'game'-N,'Texas'-^ are all correctly predicted.

However 'RT' is misclassified as a numeral probably because the word bet is used earlier on in the sentence.

':' is also misclassifed as a punctuation and it is reasonable because ':' are used for punctuations and continuations

 $\dot{}$ '@DjBlack_Pearl' is misclassified as a preposition and it a little random because the '@' signs aren not parsed.

Using those as features would fixed miclassifying of @xyz.

Question 5.9 (OPTIONAL: 4 Extra Credit points)

Improve the features of your tagger to improve accuracy on the development set. This will only require changes to local_emission_features. Implement at least 4 new types of features. Report your tagger's accuracy with these improvements. Please make a table that reports accuracy from adding different features. The first row should be the basic system, and the last row should be the fanciest system. Rows in between should report different combinations of features. One simple way to do this is, if you have 4 different feature types, to run 4 experiments where in each one, you add only one feature type to the basic system. For example:

System	Acc
basic	0.6927
basic plus first new feature	number
basic plus second new feature	number
basic plus third new feature	number
basic plus fourth new feature	number

Hint: if you make features about the first character of a word, that helps a lot for the # (hashtag) and @ (at-mention) tags. The URL tag is easy to get too with a similar form of character affix analysis. Character affixes help lots of other tags too. Also, if you have a feature that looks at the word at position t, you can make new versions of it that look to the left or right of the t^{th} position in question: for example, 'word to left=the'.
